

```
'''
Q.1) Write a Python function to check whether a string is a pangram or not.
Note : Pangrams are words or sentences containing every letter
of the alphabet at least
once.
```

```
def is_pangram(s):
    s = s.lower()
    letter = set(s)
    alphabet = set('qwertyuiopasdfghjklzxcvbnm')
    return alphabet.issubset(letter)
s = "The quick brown fox jumps over the lazy dog"
print("paragram" if is_pangram(s) else "not paragram")
```

The screenshot shows a terminal window titled "Run" with a tab for "day5test". The command prompt shows the execution of a Python script: `E:\vita_CDAC\3_PYTHON\.venv\Scripts\python.exe E:\vita_CDAC\3_PYTHON\placementprep\day5test.py`. The output of the script is `paragram`. Below the command prompt, it states "Process finished with exit code 0". On the left side of the terminal, there is a vertical toolbar with icons for running, stepping through, and other debugging actions.

For example : "The quick brown fox jumps over the lazy dog"

Q.2) Write a Python program to calculate the sum of the digits in an integer.

```
integer = 12345
a= str(integer)
print(sum(map(int, a)))
```

The screenshot shows a terminal window titled "Run" with a tab for "day5test". The command prompt shows the execution of a Python script: `E:\vita_CDAC\3_PYTHON\.venv\Scripts\python.exe E:\vita_CDAC\3_PYTHON\placementprep\day5test.py`. The output of the script is `15`. Below the command prompt, it states "Process finished with exit code 0". On the left side of the terminal, there is a vertical toolbar with icons for running, stepping through, and other debugging actions.

Q.3) Write a Python program to sort three integers without using conditional statements and loops. [u can use built in functions for this]

```
a =10
```

```

b =6
c= 4

e = min(a,b,c)
print('minimum value ',e)
f = max(a,b,c)
print("maximum value", f)
g = (a + b+ c) -(e + f)
print("middle value ",g)

```

```

Run day5test x
E:\vita_CDAC\3_PYTHON\.venv\Scripts\python.exe E:\vita_CDAC\3_PYTHON\placementprep\day5test.py
minimum value 4
maximum value 10
middle value 6
Process finished with exit code 0

```

Q.4) Write a Python function to check whether a number is perfect or not.
According to Wikipedia :

In number theory, a perfect number is a positive integer that is equal to the sum of its proper positive divisors, that is, the sum of its positive divisors excluding the number itself (also known as its aliquot sum). Equivalently,

a perfect number is a number that is half the sum of all of its positive divisors (including itself). Example : The first perfect number is 6, because 1, 2, and 3 are its proper positive divisors, and $1 + 2 + 3 = 6$. Equivalently, the number 6 is equal to half the sum of all its positive divisors: $(1 + 2 + 3 + 6) / 2 = 6$.

The next perfect number is $28 = 1 + 2 + 4 + 7 + 14$. This is followed by the perfect numbers 496 and 8128.

```

'''
def is_perfect(num):
    if num <= 1:
        return False
    total = 0
    for i in range(1, num):
        if num % i == 0:
            total += i
    return total == num

n = 28
print("Perfect Number" if is_perfect(n) else "Not Perfect Number")

```

Run day5test x

```
E:\vita_CDAC\3_PYTHON\.venv\Scripts\python.exe E:\vita_CDAC\3_PYTHON\placementprep\day5test.py  
Perfect Number  
  
Process finished with exit code 0
```
